Student self-assessment is of great interest to teachers who want their students to take more responsibility for learning by judging their own progress. This exploratory study compares self assessment, teacher assessment and peer assessment in a Japanese university EFL class. Nineteen students gave oral presentations and each student rated her own performance in terms of eight categories (loudness, eye contact, etc.). The other students also assessed the talk, as did the teacher. The three types of assessment scores were added, averaged and then compared. The results suggest that student and teacher assessment scores were similar and the scores of the higher proficiency students were more similar to the teacher scores than the lower proficiency students' scores. There was no difference in the way the male and female students judged themselves, and the self-assessment scores tended to be similar to the teacher scores.

In many educational settings, a close relationship between assessment and curriculum has developed over the past twenty years (Fradd & McGee, 1994, p. 281), and it is now commonly accepted that the learner should have a role in classroom assessment (Griffee, 1995; LeBlanc & Painchaud, 1985; Nunan, 1988). Nevertheless, student self-assessment (SSA) is still not common in the field of teaching English as a second or foreign language. This report presents the results of a

Classroom Research on the Use of Learner Self-Assessment

Self-assessment is also known as self-report, self-rating or self-evaluation and has been defined as checking one's own performance on a learning task after it has been completed (Richards, Platt, & Platt, 1992, p. 327). Wesche, Paribakht and Ready (1996, p. 199) state that "self-report procedures usually require candidates to rate their ability to do certain things using their L2, or their knowledge of particular elements or patterns of the L2."

Current trends now favor communicative language teaching. This pedagogy brings the learner to center stage (Graves, 1996, p. 24) and supports autonomous learning and the learner-centered classroom, formats which favor the use of SSA. For example, Dickinson (1993, p. 330) lists five characteristics of an autonomous learner: The autonomous learner can identify what has been taught, can formulate his own learning objectives, can select and implement his learning strategies, and can self-assess. In discussing the learner-centered classroom, Nunan (1988, p. 116) argues that both the learner and the teacher should be involved in evaluation, and Griffee's review (1995, p. 3) identifies SSA as an important characteristic of learner-centered classrooms.

Proponents of SSA offer wide-ranging justifications for its use, some of which are supported by empirical studies and some of which remain working hypotheses. These can be reduced to nine general arguments.

2. Self-assessment increases learner motivation (Rolfe, 1990, p. 169); a review of the literature (Blanch, 1988, p. 82) cites eight studies supporting this suggestion.

3. Self-assessment promotes learning by giving learners training in evaluation (Oskarson, 1989, p. 3). This occurs when learners address questions such as "What am I learning?" and "How well am I learning?"

4. The criteria for self-assessment can be directly related to course goals and objectives allowing the learner to better understand course organization (Brindley, 1989, p. 60).

5. Self-assessment can result in learners becoming more goal-oriented (Rolfe, 1990, p. 169), thereby exerting more effort to achieve their
goals, and even formulate goals themselves (Oskarson, 1989, p. 4). Within the context of given course objectives, SSA can show both learner and teacher new ways to accomplish those objectives (Legutke & Thomas, 1991, p. 243).

7. Self-assessment helps promote a cooperative classroom (Brindley, 1989, p. 60).

8. Self-assessment frees the teacher from being the only person in the classroom concerned with evaluation (Brindley, 1989, p. 60; Oskarson, 1989, p. 4; Rolfe, 1990, p. 169).

9. Self-assessment can continue after the course is finished. This is an important consideration since no single teacher or course can teach the entirety of a language. Therefore, learners must continue to acquire language through their own effort (Dickinson, 1987, p. 136; Oskarson, 1989, p. 5).

On the other hand, there have also been objections to wide-spread use of SSA. These can be summarized by the following three arguments. The first is that many learners lack the ability to self-assess and cannot do it reliably (Oskarson, 1989, p. 2). Citing Blanch and Merino (1989), Cohen (1994, p. 199) lists five factors that can threaten the validity of self-assessment, including the fact that learners may not be able to accurately report or assess what is often subconscious behavior. Second, learners may lack motivation to self-assess because of culturally-based expectations of appropriate classroom behavior and activities (Cohen, 1994, p. 199; Lynn, 1995, p. 37). Additional problems come from subjectivity and the natural desire of students to inflate their ratings, whether this is intentional or not (Brindley, 1989, p. 61; Dickinson, 1987, p. 134). A third obstacle to SSA is the lack of shared valid criteria for the learners and the teacher to use in assessment (Blanch, 1988, p. 82; Cohen, 1994, p. 199). This situation occurs when the teacher asks students to assess their work without clearly explaining the criteria which must be used. The lack of learner training in assessment (Cohen, 1994, p. 199) is related to this lack of criteria and probably results from unwarranted teacher assumptions that learners have the tools for self-assessment (LeBlanc & Painchaud, 1985, p. 675).

Such objections account for teacher skepticism (Brindley, 1989, p. 60) and, when combined with the natural fear of change (Rojas, 1995, p. 32), may account in part for the lack of SSA in many classrooms today.
However, many of these objections are based on teacher supposition rather than actual research findings. For example, a study using confirmatory factor analysis and a multitrait-multimethod design (Bachman & Palmer, 1989, p. 22) reports that self-ratings can be a reliable and valid measure of communicative language ability.

Regarding the question of consistent agreement between individual self-assessments and other sources, a review of 16 articles (Blanch, 1988, p. 81) reported a pattern of consistent agreement between SSA and a variety of external criteria. However, other research findings are less positive. A study of adult learners of various linguistic backgrounds in Australia (Rolfe, 1990, p. 177) reported that students consistently rated themselves lower than their peers' ratings. Whereas Dickinson (1987, p. 150) suggested that learners are biased in their own favor, Rolfe (1990, p. 178) concluded that learners are more critical of themselves than their teachers are; thus SSA was not a reliable indicator of oral ability as compared to teacher-assessment (TA). In comparing SSA to peer-assessment (PA), Rolfe reported that the PA may therefore be more reliable. Falchikov and Boud (1989, p. 398) investigated whether fourth year university students were more accurate in their SA than first year students and concluded that they were not. This is in accord with the findings of Griffee (1996, p. 32), who reported on a classroom SSA project in which there was no major difference in self-evaluations among first-year, second-year, and third-year oral conversation classes at a Japanese university. Relative to possible differences in male and female responses to self-assessment, Falchikov and Boud (1989, p. 396) concluded that gender differences are under-researched and that no conclusions can be drawn. They also question whether learners overestimate or underestimate themselves relative to teacher assessment, and stress the need for further research investigating the reliability of self-assessment among different groups of learners as well as the development of methods to improve the learners' ability to accurately estimate their performance.

The Study

Research Questions

The purpose of this exploratory study is to examine the operation of SSA in a Japanese university EFL classroom setting. The specific research questions are:

1. To what extent will SSA, PA, and TA test scores agree?
2. Will there be a higher level of agreement between more proficient
students and the teacher than between less proficient students and the teacher?

3. Will there be any gender differences in self-assessment?

4. Will SSA be higher or lower than TA?

**Methods**

**Subjects:** The students who participated in this study were enrolled in the second semester of a first-year required English oral conversation course at a small liberal arts university in Japan. The total class enrollment was 24, with 12 females and 12 males, but only 19 students were present during the two class periods when the study was conducted. The majority of the students were 18 or 19 years old. The subjects' Secondary Level English Proficiency (SLEP®) test scores averaged 42.0, which is equivalent to 400 on the TOEFL®. The SLEP® test scores were used to divide the students into high-proficiency and low-proficiency groups in the following way: The four subjects with scores of the mean value 42 were eliminated, leaving 10 students with scores over 42, eight of whom gave oral presentations and 10 students with scores under 42, seven of whom gave oral presentations. The presentation theme for all students was "How I study vocabulary."

**Materials:** A short score sheet (see the Appendix) was constructed which asked students to evaluate each oral presenter on eight points within three categories—voice, body language, and content. Under the category of "voice," the points to be rated were loudness, clarity, and speed; under "body language," the points were eye contact and gestures; under "content," the points were introduction, interesting talk, and conclusion. Each point could be rated on a Likert-type scale with values from one to three, with three as the highest score.

**Procedures:** A 45-minute training session was conducted by a Japanese native speaker and an English native speaker. Each category was explained in some detail in both Japanese and English, then each of the eight evaluation points was illustrated by the English native speaker in all three conditions and discussed by the Japanese native speaker.

The students were then assigned the oral presentation topic and two class sessions were spent making the oral presentations. When making the oral presentation, the student came to the front of the room and stood behind the teacher's desk. The talk had no time limit, although most talks were completed in under five minutes. After the oral presentation, the teacher, the student giving the talk, and the rest of the students completed their score sheets.
Analysis

Pearson product-moment correlations were used to analyze the individual self-assessment, the PA, and the TA scores, with the alpha level set at .05. Use of the Pearson correlation procedure assumes the presence of interval scales, equivalent reliability, independent data, a normal distribution, and a linear relationship (Hatch & Lazaraton, 1991, p. 549). To check these assumptions, descriptive statistics were generated by StatView 4.5 for the Macintosh (1992). Correction for attenuation\(^1\) was done using the formula from Guilford and Fruchter (1973, p. 439). The non-parametric Wilcoxon Signed Rank Test was also used to determine if there was any difference between the SSA scores and teacher scores. Cronbach's alpha, a measure of reliability, and the standard error of measurement (SEM) were calculated on a spreadsheet from the formula provided in Brown (1996, p. 196).

Results

The descriptive statistics reveal similarities between the SA and the TA scores (Table 1), with a mean assessment score of about 1.8 for each group. However, the mean PA score of 2.28 was higher than both SA and TA scores. The SLEP\(^*\) scores formed a fairly normal distribution. Therefore, a Pearson correlation was calculated for both groups of students between their SA scores and the teacher scores to determine which group's ratings was closest to the ratings of the teacher. The correlation between the higher proficiency students' scores and the teacher scores

was .241 \((p < .0547)\), whereas the correlation between the lower proficiency students' scores and the teacher scores was .187 \((p < .695)\). To determine whether there was a significant difference between all SSA scores and TA scores, a Wilcoxon Signed Rank Test was performed. The results \((z = -.575, p < .5653)\) indicate that there was no significant difference between the two sets of scores.

Pearson correlations between the total scores for student assessment, PA, and TA were calculated and corrected for attenuation (Table 2). A low correlation was found between SSA and TA, a slightly higher correlation was found between SSA and PA, and a relatively strong correlation was found between PA and TA. R square, which is the Pearson correlation coefficient squared and expressed as a percentage, gives an indication of the magnitude of the relationship. The figure of six percent for the relationship between the SSA scores and the teacher assessment scores indicates that only six percent can be accounted for by the correlation, whereas 13% of the relationship between SSA and PA is explained, and 42% of the relationship between SSA and TA is accounted for by the correlation, as shown below.

To investigate the existence of gender differences in assessment score values, the scores were totaled for each student and the number of student scores that were higher and lower than TA scores was counted (Table 3). To account for standard error, if the difference between higher than TA and lower than TA scores was plus or minus one, these values were eliminated and the resulting scores are referred to as adjusted scores. There were 12 students who rated themselves higher than the teacher's ratings, and seven students who rated themselves lower. After eliminating the scores with values of plus or minus one from the teacher's scores, there were ten students who rated themselves higher than the teacher and six students who rated themselves lower. Of the ten who rated themselves

higher, five were males and five were females. Of the six who rated themselves lower, three were males and three were females. Thus, there were no gender differences in scoring in the restricted sample used here.

Discussion

The first research question asked whether the SSA, PA, and TA test scores agreed. The descriptive statistics show that the SSA scores were similar to the TA scores. The correlations in Table 1 indicate a low correlation between the SSA and TA, a modest agreement between SSA and their peers, and a higher agreement between PA and TA. On the face of it, this would seem to suggest that students did not agree with the teacher in their assessment of themselves, whereas, as a group evaluating each other (PA), their scores were similar to their teacher's scores. However this result should be interpreted cautiously. The SSA and teacher scores suffered from restriction of range, suggesting that the correlation coefficients were very likely depressed. The use of a limited Likert scale, with values of only one to three, produced the low variance. The relationship between SSA and TA therefore requires further investigation using a larger number of subjects and an instrument with a greater number of choices, permitting more variance.

The second research question asked whether higher proficiency learners would exhibit better agreement between their self-evaluations and the teacher evaluations than the lower proficiency group. The answer to this question was inconclusive. The correlation between the teacher scores and the higher ability students scores ($r = .241; p < .05$) was higher than the correlation between the lower ability students and the teacher ($r = .187; p < .70$), but was not statistically significant.

The third research question involved the impact of gender on the evaluation process. As shown in Table 3, the number of male students who rated themselves higher or lower than the teacher was exactly the same as the number of female students who scored themselves higher
or lower. In this limited study, gender was not significant, but it should be noted that the number of subjects was low.

Research question four asked whether the SSA scores would be higher or lower than the teacher scores. The results indicate there was no difference between SSA scores and teacher scores. This suggests that students were assessing themselves in a manner similar to the teacher and provides some support for the validity of SSA, keeping in mind the limitations of this pilot study.

Conclusion

Problems with the present study include the restricted Likert scale which produced a narrow band of scores, the small number of subjects, and the use of a data collection instrument which was not validated. Therefore the findings reported here are not generalizable. Nevertheless, this preliminary study is encouraging in that the student peer-assessment appears to be similar to teacher assessment in the group studied. Suggestions for future research include use of a validated data collection instrument, a much larger number of subjects and a five-point Likert scale to increase the score range. There is also a clear need for longitudinal studies which examines the effect of experience and training on student assessment.

Acknowledgments

Thanks are due to Sonta Yoshitake for help in the training session and J. D. Brown for help in calculating the correction for attenuation.

Dale T. Griffee teaches at Seigakuin University. His major research interests are curriculum and evaluation and he has edited (with David Nunan) Classroom Teachers and Classroom Research in the JALT Applied Materials series. He can be contacted at Seigakuin University, 1-1 Tosaki, Ageo-shi, Saitama-ken 362 or by e-mail: <Dale_Griffee@ringo.net>.

Notes

1. Attenuation is a correction for reliability applied to a correlation coefficient. Correlation assumed perfect reliability. If the reliability is .70, this means that 30% of the score is error which lowers the correlation coefficient. Attenuation takes this into account.
